## Approaches for Evaluating the Application Performance of Future Mobile Networks

### ITG 5.2.4 — July 2011 — Aachen

Thomas Werthmann, Matthias Kaschub, Christian Blankenhorn, and Christian M. Mueller thomas.werthmann@ikr.uni-stuttgart.de

Universität Stuttgart Institute of Communication Networks and Computer Engineering (IKR) Prof. Dr.-Ing. Andreas Kirstädter

### Outline

**Motivation & Problem Statement** 

**Approaches** 

**Our Implementation** 

Conclusion

#### **Subject of evaluation**

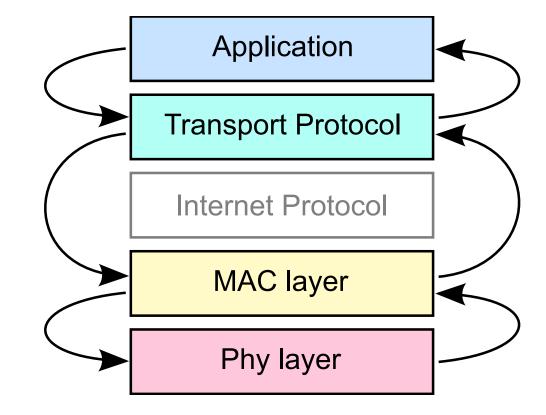

Algorithms and techniques in the Phy and MAC layers

#### **Metric**

- Achievable application performance
- Difficult to derive from average delay & throughput
- $\rightarrow$  Models required for evaluation

#### Feedback to lower layers

- Object sizes transmitted by applications
- Effects from parallel TCP connections
- Queues running empty

Application Performance of Future Mobile Networks

**Cross-Layer evaluation required** 

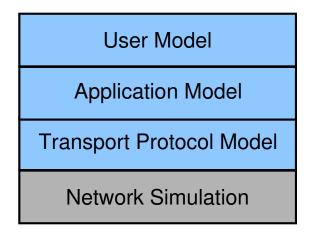

How to bring network simulation and real world protocols / applications together?

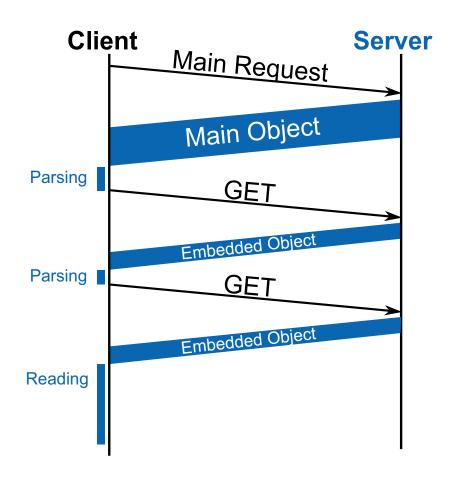

## Approaches (1/3)

Model all components

# Simulation models for Applications and Transport Protocols

- TCP models: various implementations
- Application models:
  e.g. NGMN web model (on the right)
- $\rightarrow$  complicated algorithms
- $\rightarrow$  models usually simplified still realistic?

### Approaches (2/3)

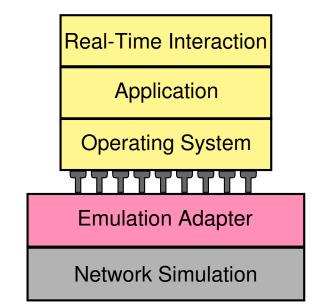

Bring the network simulation into a lab setup

#### **Real-Time Emulation**

- Build up lab setup with real computers
- Connect real network devices to simulated network
- Optionally communicate with the real internet
- $\rightarrow$  Requires fast (abstract) simulation models

#### **Slowed Emulation**

- Decelerate the computers' clock speed to gain time for emulation
- $\rightarrow$  Requires special setup & synchronization

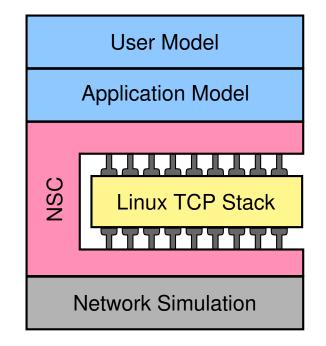

### Approaches (3/3)

### Bring real code into the Simulation

#### **Example: Network simulation cradle**

- Linux kernel code is modified by partly automated scripts
- TCP stack can be loaded as shared library into ns-2
- Clocks of the kernel are driven by the simulation
- $\rightarrow$  Adapts to the speed of the simulation
- $\rightarrow$  Authentic protocol behavior
- → The chosen interface makes it difficult to port a new linux kernel

## **Our Approach**

#### **Existing IKR Simulation Ecosystem**

- IKR SimLib  $\rightarrow$  fixed network simulation
- IKR RadioLib  $\rightarrow$  radio transmissions (LTE)
- IKR EmuLib  $\rightarrow$  real time emulation
- IKR nscadapter  $\rightarrow$  wrapper for the NSC
- QEMU simulation adapter

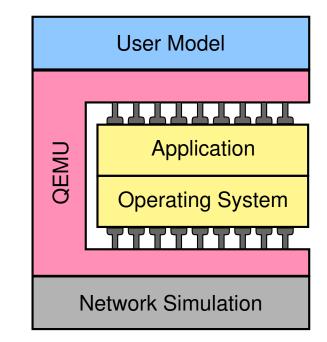

#### Main Idea

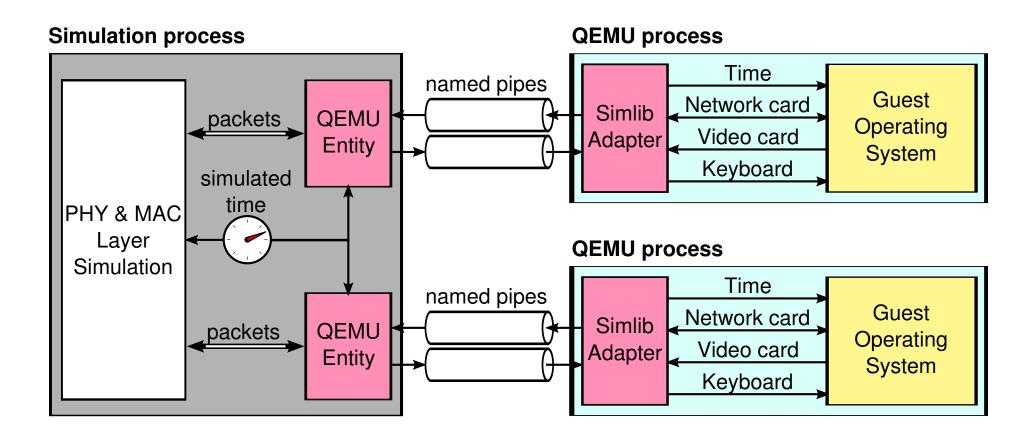

- Use Computer Virtualization as interface between simulation and real code
- Let virtual clock be driven by the simulation

#### **Our ambition**

- Easy handling (hundreds of simulations)
- No special requirements for hardware etc.

# → Possible to perform simulations on a standard computer cluster

#### $\rightarrow$ Independent processes communicating via pipes

### **QEMU** as interface between Simulation and OS

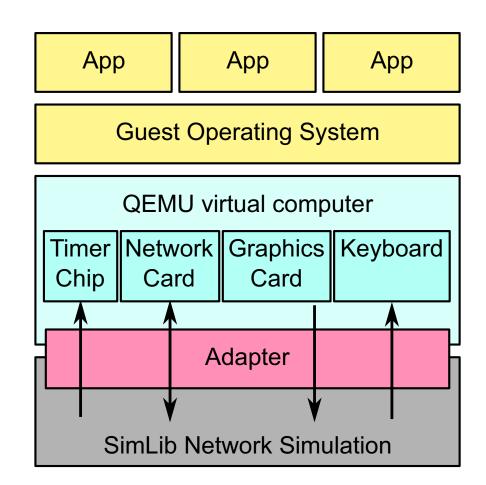

#### **Virtual Computer as Interface**

Operating system and applications do only see the virtual computer

- $\rightarrow$  No modifications required
- $\rightarrow$  Easy to install new applications / OSs

#### **Modifications inside QEMU**

- Layered architecture: QEMU consists of device emulations and backends
- Our adapter provides additional backends, emulation layer remains unchanged
- We have modified the QEMU main loop to support a shared control flow

### **Control Flow**

#### Interaction of SimLib and QEMU

- Either the simulation or one single QEMU instance executes at a time
- Timer events correspond to events in the simulation calendar
- Calculations inside the virtual computer are performed in zero simulated time
  - → follows paradigm of event-driven simulation
- Virtual computer can spend nearly infinite time for computations
- SimLib Qemu event timestamp event CPU idle event network packet event CPU idle
- $\rightarrow$  Virtual computer is not restricted by host CPU power
- $\rightarrow$  Strictly synchronous interaction

### **User Model and Metrics**

#### **User Models**

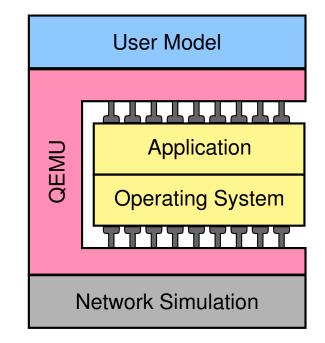

- Interactive use not desired and not possible
- → Automatic user models required (e.g. stochastic reading time)

#### **Subjective Metrics**

- Record and play back screencast
- Compare different parametrizations

#### **Objective Metrics**

- Automatically analyze screenshots (e.g. determine if pixels change)
- Investigate network packets (e.g. first and last packet of a TCP session)
- Modify applications to print their state in a machine-readable format

#### Memory

- Overhead of emulator and adapter: negligible
- Small operating system without GUI: 32MB per instance
- Modern operating system with graphical applications: at least **512MB per instance**
- Requirements can possibly be reduced with Linux Kernel Samepage Merging (KSM)

#### **Processing Power**

- High CPU load: User space QEMU about factor 10 slower than host computer Example: booting Ubuntu Maverick takes about 15 minutes
- Low CPU load: About factor 10 faster than real time
- Typically no CPU-intensive applications on the virtual computer
- Simulated time spans have to be large to capture the upper layer effects
- $\rightarrow$  Complex Phy models become the limiting factor

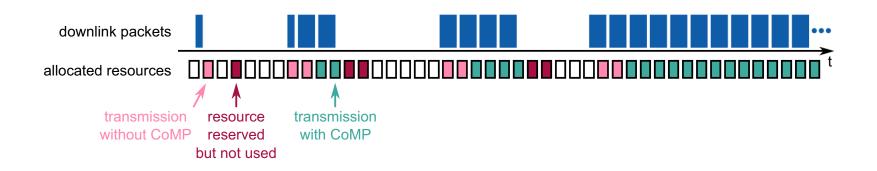

### **Usage Scenarios (1/2)**

#### Link layer evaluation of a complex MIMO setup scheme

- Focus: Influence of setup time on application performance
- Moderately abstract Phy model
- Application: Web browser loading a single web page
- Metric: Time it needs to load the web page
- Multiple drops to achieve statistically valid results
  - Simulated time: 15 seconds rate diversity spatial multiplex 1st packet

#### **Evaluation of a coordinated scheduling algorithm**

- Focus: Interactions between coordination and TCP control loops
- Abstract Phy model
- Application: Simplified  $\rightarrow$  TCP downloads only
- Stochastic models for reading times and web object sizes (including heavy tail)
- Metric: Object finish times, miscoordinated frames
- Simulated time: 2 to 8 hours

#### Summary

- Cross layer evaluation required
- Modelling of all effects is difficult
- Using real code is often easier
- Presented architecture allows to use OSs and applications without modification

#### Conclusion

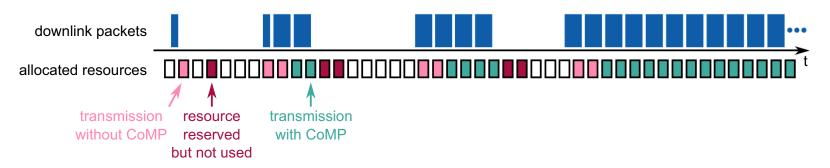

- Easy to try new applications just install on the virtual computers
- Easy to use new kernel versions
- Also nice for demonstration!
- Abstract Phy models still required because of long simulation time spans

Application Performance of Future Mobile Networks

#### A simple CoMP setup scheme

- Assuming a non-negligible communication delay between cells
- CoMP setup is started when first package arrives
- Packets are transmitted without CoMP until setup has been completed
- When the queue runs empty, the reserved resources have to be freed

#### **Influencing factors**

- TCP behavior
- Parallel TCP connections used by the Browser
- Interactive web applications requesting small objects

Application Performance of Future Mobile Networks

#### How many clock cycles per timer tick?

- Emulator has overhead  $\rightarrow$  typically slower than host
- We slow down the virtual clock anyway
  - $\rightarrow$  arbitrary time for computation available

#### How much processing power do we want?

- Exact counting of instructions is not possible with QEMU
- End device not in the focus of our evaluations
- $\rightarrow$  Model (nearly) infinite processing power

#### **Problem: infinite loops**

- Example: Linux kernel calibrating bogomips
- QEMU has to return control flow eventually
- We use a variable time-out, e.g. max. 1s CPU time per 1ms tick
